Appendix A: Methods

Cardiac procedures in hospital

The cardiac procedures examined in this report are coronary angiography, coronary artery bypass grafts and percutaneous coronary intervention (PCI).

Coronary angiography

Coronary angiography (also known as coronary arteriography) gives a picture of the heart’s arteries, known as the coronary arteries. It is used to diagnose coronary heart disease and is essential before either coronary artery bypass surgery or PCI.

Coronary artery bypass grafts (CABG)

Coronary artery bypass grafting (CABG) usually involves opening a patient’s chest and using blood vessel grafts to bypass blockages in the coronary arteries and restore adequate blood supply to the heart muscle. The graft material is usually taken from the chest wall or veins in the patient’s legs, or both. CABG is a treatment and not a cure for coronary artery disease, and there is a risk of recurrent disease. Re-operations are uncommon within the first 5 years but become more frequent later.

Percutaneous coronary intervention (PCI)

Percutaneous coronary intervention (also known as coronary angioplasty), as with coronary artery bypass surgery, is used to restore adequate blood flow through blocked coronary arteries. It involves inserting a catheter with a balloon into a narrowed coronary artery. The catheter is first inserted into a leg (or occasionally, arm) artery through the skin and then is threaded through the vessels back towards the heart and into the coronary arteries to the area of vessel blockage. The balloon is then inflated against the blocked area to create a wider passage for blood flow. The development of other catheter-based techniques, particularly stenting to the vessel wall at the site of the blockage, has reduced early acute closure of the coronary artery and restenosis.

PCI avoids the major trauma of CABG surgery because it does not require the opening of the patient’s chest. However, the technique cannot be used to treat all patients with coronary artery obstruction.

Cause of death and hospital diagnosis classification

Australia uses the International Statistical Classification of Diseases and Related Health Problems, Tenth Revision (ICD-10) for coding of causes of death. For hospital diagnosis and procedures this international classification has been modified for Australia (ICD-10-AM – International Statistical Classification of Diseases and Related Health Problems, Tenth Revision,
Australian Modification). The table below lists the ICD-10 disease and procedure codes used in this report.

Rates

This report presents age-specific rates, crude rates and age-standardised rate ratios in examining the level of inequality between Indigenous Australians and other Australians. These analytical concepts are described below.

Age-specific rates

Age-specific rates were calculated by dividing the number of events (such as incidence, hospitalisations or deaths) occurring in each specified age group by the population at risk for the corresponding age group. The ABS Experimental Projections of the Aboriginal and Torres Strait Islander Population and the Australian Estimated Resident Population for the years 2002 and 2003 were used in calculating population-based rates.

Crude rates

Crude rates were calculated by dividing the total number of events (such as incidence, hospitalisations or deaths) by the total population at risk.
Age-standardised rate ratios

Age-standardised rate ratios for incidence and hospitalisations were used to remove the influence of age when comparing populations with different age structures. Excess number of events and excess % (measures of inequality impact) for all ages have also been age-standardised. In this report, indirect age standardisation has been used, as the Indigenous Australian population is relatively small and there is some uncertainty about the stability of age-specific rates. The ‘other Australians’ population has been used as the standard population and the Aboriginal and Torres Strait Islander population has been used as the study population in these analyses. The method used for indirect age standardisation entails three steps:

Step 1: Calculate the age-specific rates for each age group in the standard population.

Step 2: Apply these age-specific rates to the number in each age group of the study population and sum to derive the total expected number of cases for the study population.

Step 3: Sum the observed cases in the study population and divide this number by the expected number derived in Step 2 to calculate the rate ratio.

A rate ratio of 1 indicates the same number of observed cases as were expected, suggesting rates in the study and standard populations are similar. A result greater than 1 indicates more cases than expected. A result less than 1 indicates fewer cases than expected. For example, if there are twice as many deaths as expected (age-standardised rate ratio of 2.0) then the rate of death in Indigenous Australians can be assumed to be twice that of other Australians.

Inequality measures—worked example

There are a number of measures that can be used to indicate the level of health inequality between population groups. In this report we use the rate ratio, rate difference, excess and excess %. Further information on how these measures relate to each other and their interpretation are provided in the Chapter 2. Below is a summary of how these are calculated.

Figure A1 provides a hypothetical example of rates for a health outcome, where the rate for Aboriginal and Torres Strait Islander people is assumed to be 300 per 100,000 and the rate for other Australians is 100 per 100,000. The hypothetical population sizes are 500,000 for Indigenous Australians, and 10 million for other Australians. Figure A1 is used to explain the various inequality measures presented in this report.

</tbody>
</table>

Aboriginal and Torres Strait Islanders (pop = 500,000) Other Australians (pop = 10 million)

Figure A1: Hypothetical rates
Rate ratio: a ratio to indicate the relative gap

Calculation: Rate for Indigenous Australians divided by rate for other Australians

\[ \frac{A}{B} \]

Worked example from hypothetical

\[ \frac{A}{B} = 300 \text{ per 100,000}/100 \text{ per 100,000} \]
\[ = 3 \]

Interpretation: the rate for Indigenous Australians is 3 times as high as for other Australians.

Rate difference: difference indicates the absolute gap

Calculation: Rate for Indigenous Australians minus the rate for other Australians

\[ A - B \]

Worked example from hypothetical

\[ A - B = 300 \text{ per 100,000} - 100 \text{ per 100,000} = 200 \text{ per 100,000} \]

Interpretation: for Indigenous Australians, there are 200 extra cases per 100,000 population compared with other Australians.

Excess: the number of cases that would have been avoided if the rate for other Australians applied to the Indigenous Australian population

Calculation: Rate difference converted to absolute number of cases

\[ (A - B) \times \text{Indigenous population} \]

This is equivalent to the observed number of cases for Indigenous Australians minus the expected number that would have occurred if the rate for other Australians had applied

\[ = \text{observed cases} - \text{expected cases} \]
\[ = A \times \text{Indigenous population} - B \times \text{Indigenous population} \]

Worked example from hypothetical

\[ A \times \text{Indigenous pop} - B \times \text{Indigenous pop} \]
\[ = 300/100,000 \times 500,000 - 100/100,000 \times 500,000 \]
\[ = 1,500 - 500 = 1,000 \]

Interpretation: there were 1,000 cases that would have been avoided if the rate for other Australians had applied to the Indigenous population.

Excess %: the per cent of cases among Indigenous Australians that would have been avoided if the rate for other Australians had applied.

Calculation: Excess Indigenous cases as a percentage of all Indigenous cases

\[ \frac{A - B}{A} \times 100 \]

Worked example from hypothetical

\[ \frac{A - B}{A} \times 100 \]
\[ = (300 \text{ per 100,000} - 100 \text{ per 100,000})/300 \text{ per 100,000} \times 100 \]
\[ = 200/300 \times 100 = 67\% \]

Interpretation: 67% of Indigenous Australian cases would have been avoided if the rate for other Australians had applied to the Indigenous population.
## Appendix B: Statistical tables

### Table B1: Population estimates for Qld, WA, SA, and NT, 2002–2003

<table>

</tbody>
</table>

(a) Includes those aged less than 25 years.

*Note:* Indigenous population has been obtained from the Experimental Projections of the Aboriginal and Torres Strait Islander population at 30 June 2002 and 2003. Other Australians population has been estimated from the difference between the estimated resident population at 30 June 2002 and 2003 and the experimental projections of the Aboriginal and Torres Strait Islander populations (2002 and 2003).

</table>

\(^{(a)}\) Includes those aged less than 25 years.

**Note:** Comorbidities studied include diabetes, hypertensive diseases, high cholesterol, heart failure, chronic kidney failure, chronic obstructive pulmonary disease, chronic rheumatic heart disease or other valve disorders, and cerebrovascular disease.

**Source:** AIHW National Hospital Morbidity Database.
Glossary

**Aboriginal**  A person who identifies as an Aboriginal and is accepted as such by the community in which he or she lives.

**Aboriginal and Torres Strait Islander people** and **Indigenous Australians**  Terms used interchangeably when referring to people who have identified as Aboriginal and/or Torres Strait Islander.

**Acute myocardial infarction (AMI)**  A condition where part of a person’s heart muscle dies as a result of a blood clot that completely blocks the flow of blood to that part.

**Additional diagnosis**  Conditions or complaints either co-existing with the principal diagnosis or arising during the episode of care.

**Age standardisation**  A method of removing the influence of age when comparing populations with different age structures. Indirect age standardisation has been used in this report. A standardised ratio is calculated by comparing the actual number of events with the number expected if the age-specific rates in the ‘other Australians’ population applied to the Indigenous population. A ratio of greater than one indicates more events than expected, whereas a ratio of less than one indicates fewer events than expected.

**Age-specific rate**  A rate for a specific age group. The numerator and denominator relate to the same age group.

**Angina**  Temporary chest pain or discomfort when the heart’s own blood supply is inadequate to meet extra needs, for example during exercise.

**Case fatality**  An important outcome measure which quantifies the proportion of cases that are fatal within a specific time period. Overall case fatality used in this report relates to major coronary events and is calculated as the number of CHD deaths in the specified population divided by the sum of all CHD deaths and non-fatal hospital admissions for AMI (with length of stay of 3 days or more) for the period 2002–2003.

**Cerebrovascular disease**  See stroke.

**Chronic obstructive pulmonary disease (COPD)**  Serious, progressive and disabling long-term lung disease where damage to the lungs, usually due to both emphysema and chronic bronchitis, obstructs oxygen intake and causes increasing shortness of breath. By far the greatest cause is cigarette smoking.

**Chronic renal failure**  Long-term condition where kidney function is lost progressively and irreversibly. End-stage renal disease is the final stage in the progressive deterioration of kidney function. In this situation, a person needs dialysis or a kidney transplant to remain alive.

**Chronic rheumatic heart disease**  Long-term damage done to the heart muscle or heart valves by acute rheumatic fever. Acute rheumatic fever is a delayed complication of an untreated throat infection with group A streptococcus (GAS) bacteria. It can affect the heart valves, the heart muscle and its lining, the joints and the brain.

**Comorbidity**  In this report this term is used to describe the existence of a select list of conditions recorded as an additional diagnosis on the hospital record.

**Coronary angiography**  A diagnostic procedure which gives a picture of the heart’s arteries.
Coronary artery bypass grafting (CABG)  Surgical procedure using blood vessel grafts to bypass blockages in the coronary arteries and restore adequate blood flow to the heart muscle. Also see percutaneous coronary intervention.

Coronary heart disease (CHD)  Its primary feature is insufficient blood supply to the heart itself. The two major clinical forms are heart attack (the insufficient blood supply is sudden and extreme) and angina. The underlying problem is atherosclerosis, a complex process where fatty and fibre-like deposits build up on the inner walls of the arteries, often forming plaques. CHD is also known as ischaemic heart disease.

Coronary stent  A metal mesh tube that is expanded within an artery at a point of narrowing and left there to hold the artery open.

Crude rate  Calculated by dividing the total number of events (such as incidence and hospitalisations) by the total population at risk.

Diabetes (diabetes mellitus)  A chronic condition in which the body makes too little of the hormone insulin or cannot use it properly. This raises the blood level of the body’s major energy source, the sugar glucose, and causes other widespread disturbance of the body’s energy processes.

Excess number of cases  An absolute measure of the impact of inequality calculated as the difference between the observed and expected number of cases. It represents the number of cases that would have been avoided if the rate for other Australians applied to the Indigenous population.

Excess %  A relative measure of the impact of inequality. It is calculated as the excess number of cases as a percentage of all Indigenous cases and is interpreted as the percentage of Indigenous cases that would have been avoided if the rate for other Australians applied to the Indigenous population.

Heart attack  Life threatening emergency that occurs when a vessel supplying blood to the heart muscle is suddenly blocked completely by a blood clot. The medical term commonly used for a heart attack is acute myocardial infarction.

Heart failure  When the heart cannot pump strongly enough to keep the blood circulating around the body at an adequate rate.

High blood cholesterol  It is the main cause of the process by which the blood vessels that supply the heart and other parts of the body become clogged.

Hypertensive disease  Disease occurring when high blood pressure (hypertension) is severe or prolonged enough to cause damage to the heart, brain or kidneys.

Incidence  The number of new cases of a condition or disease occurring in a population within a specified time period.

Incidence of major coronary events  Estimated as the sum of the number of non-fatal hospital admissions for AMI (with length of stay of 3 days or more) and the number of deaths recorded as CHD deaths.

Indigenous  A person who identifies as Aboriginal and/or Torres Strait Islander and is accepted as such by the community with which he or she lives.

In-hospital fatality rate  This refers to the proportion of hospitalised cases that die in hospital. In-hospital fatality for CHD used in this report is defined as the number of CHD deaths in hospital in those hospitalisations where CHD is the principal diagnosis divided by the number of hospitalisations with CHD as the principal diagnosis.
International Classification of Diseases  The World Health Organization’s internationally accepted classification of death and disease. The 10th Revision (ICD-10) is currently in use.

Length of stay  Duration of hospital stay, calculated by subtracting the date the patient is admitted from the date of separation. All leave days, including the day the patient went on leave are excluded. A same-day patient is allocated a length of stay of 1 day.

Major coronary event  An event that results either in an acute admission to hospital for acute myocardial infarction (AMI) with a length of stay of 3 days or more, or in death from CHD. It should be noted that this excludes admissions for unstable angina or for coronary revascularisation procedures where the principal diagnosis is not AMI.

Morbidity  Refers to ill health in an individual and to levels of ill health in a population or group.

Mortality  Death

Other Australians  This term is used when referring to people that have not identified as Aboriginal and/or Torres Strait Islander. This group will include those people who have said they are non–Indigenous but may also include either Aboriginal and/or Torres Strait Islander people who have chosen not to identify as such or individuals for whom the relevant information was not collected.

Out-of-hospital fatality rate  This refers to the proportion of cases that result in death without admission to hospital or after discharge from hospital. Out-of-hospital fatality used in this report is estimated as the total number of deaths from CHD less the number of CHD deaths in hospital in those hospitalisations where CHD is the principal diagnosis divided by the sum of all CHD deaths and non-fatal hospital admissions for AMI (with length of stay of 3 days or more). It should be noted that deaths occurring in the emergency departments of hospitals are included in this group, as these deaths occur before the formal admission to hospital takes place.

Overweight  Defined as a body mass index 25 and over.

Percutaneous coronary intervention (PCI)  Coronary angioplasty and coronary stenting when used together are referred to as PCI. It is used to restore adequate blood flow to blocked coronary arteries. Coronary angioplasty involves inserting a catheter with a balloon into a narrowed coronary artery. The balloon is then inflated against the blocked area to create a wider passage. Coronary stenting involves expanding a metal mesh tube within the artery to form a supporting structure to hold the artery open at the point where there is narrowing. Also see coronary artery bypass grafting and coronary stent.

Principal diagnosis  The diagnosis established, after study, to be chiefly responsible for the patient’s episode of care in hospital; that is, the main or primary diagnosis.

Rate difference  Absolute measure of inequality which is calculated as the rate for Indigenous Australians minus the rate for other Australians.

Rate ratio  Relative measure of inequality which is calculated as the rate for Indigenous Australians divided by the rate for other Australians. For the age-standardised case, it is the ratio of the observed to the expected number of cases had the rates for other Australians applied.

Revascularisation (‘re-vesselling’)  Restoring adequate blood flow to the heart or other part of the body, usually after the supply has been reduced or blocked, as in angina or a heart attack. Revascularisation includes methods such as PCI and coronary artery bypass graft surgery.

Separation  The formal process by which a hospital records the completion of treatment and/or care for an admitted patient.
**Stroke**  When an artery supplying blood to the brain suddenly becomes blocked or bleeds. Often causes paralysis of parts of the body normally controlled by that area of the brain, or speech problems and other symptoms.

**Torres Strait Islander**  A person who identifies as a Torres Strait Islander and is accepted as such by the community in which he or she lives.

**Underlying cause of death**  The condition, disease or injury initiating the sequence of events leading to death, that is, the primary, chief, main or principal cause.

**Unstable angina**  A form of *angina* that is more dangerous than normal angina but less so than a *heart attack*. It can feature chest pain that occurs at rest; and in someone who already has angina it can be marked by new onset of chest pain with exertion or pain that accelerates by coming on more easily, more often or for longer than previously.
