## Preface

Despite great improvements in death rates in recent decades, cardiovascular disease remains Australia's greatest health problem.

Cardiovascular disease kills almost 54,000 Australians each year, primarily as a result of ischaemic heart disease, cerebrovascular disease and peripheral vascular disease. Ischaemic heart disease and cerebrovascular disease alone claim a life every 12 minutes. The direct costs of health care, which include hospital, nursing home, medical and pharmaceutical costs, amounted to \$3.7 billion in 1993–94. Of particular concern are the demand on health resources for the invasive management of heart disease, and the heavy burden of disability due to stroke. Also, many Australians remain at higher risk of cardiovascular disease through cigarette smoking, high blood pressure, high blood cholesterol, overweight and insufficient physical activity.

For reasons such as these, Australian Health Ministers made cardiovascular health one of five National Health Priority Areas (the others are cancer control, injury prevention and control, mental health and diabetes mellitus). The Commonwealth Department of Health and Family Services also funded the Australian Institute of Health and Welfare to establish a national system to monitor cardiovascular disease, its risk factors and management. The system was set up in 1996 and comprises a National Centre for Monitoring Cardiovascular Disease (based at the Institute), an Advisory Committee and a number of collaborative projects with other centres.

This report on cardiovascular disease mortality, prepared within the National Centre, addresses one of the important functions of the monitoring system: to monitor and report on trends and differentials in cardiovascular mortality. It is the sixth in the Institute's Cardiovascular Disease Series. Patterns and trends in cardiovascular disease mortality among Aboriginal and Torres Strait Islanders and urban, rural and remote areas have been included for the first time in this series, in addition to national and State and Territory data.

## Acknowledgements

The authors gratefully acknowledge the assistance and support received from individuals in various government organisations who contributed to the production of this report.

The following people provided comments on draft material and their input is greatly appreciated: Dr Ian Ring, Epidemiology and Prevention Unit at the Queensland Department of Health; Dr Glenn Close, Clinical Policy and Practice Unit at the NSW Department of Health; Dr Joan Cunningham, National Centre for Aboriginal and Torres Strait Islander Statistics at the Australian Bureau of Statistics; and Dr Paul Magnus, Principal Medical Adviser at the Australian Institute of Health and Welfare.

The invaluable assistance of other colleagues within the Institute is also gratefully acknowledged, particularly that of Dr Stan Bennett, Head of the National Centre for Monitoring Cardiovascular Disease, who originally designed the mortality surveillance system and critically reviewed draft versions of this report. Other staff from the National Centre are also acknowledged for their constructive comments and editorial suggestions, in particular Melinda Petrie.

# Summary

This report on surveillance of cardiovascular disease mortality, prepared within the National Centre for Monitoring Cardiovascular Disease, addresses one of the important functions of the monitoring system: to monitor and report on trends and differentials in cardiovascular mortality. It provides a detailed statistical profile of patterns and trends in cardiovascular disease mortality for Australia, each State and Territory, Indigenous and non-Indigenous people and people living in urban, rural and remote areas of Australia. The main findings of the report are:

## Australia

Cardiovascular disease continues to be the leading cause of death in Australia, although death rates are falling in all ages for males and females.

- In 1996, cardiovascular disease accounted for 53,990 deaths or 42% of all deaths among Australians.
- Cardiovascular mortality has been declining over recent decades, with current annual rates of decline at 3.7% for males and 3.6% for females, over the period 1985–1996. The decline in cardiovascular mortality is more rapid than that for total mortality.
- Death rates from cardiovascular disease are declining in all age groups, but the decline is most rapid in the 45–59 age group (over 6% per year).
- Ischaemic heart disease remains the major cardiovascular cause of death (55% of such deaths), and is declining at a rate of 4% per year for males and 3.6% for females.
- If current trends continue, Australian death rates for premature mortality (25–74 years) from ischaemic heart disease will be very close to national targets for the year 2000.

## States and Territories

Age-standardised death rates for cardiovascular disease vary between States and Territories within 20% of the national average. Death rates are falling in all States and Territories but more slowly in the Northern Territory. This slower rate of decline is attributed to the large proportion of Indigenous people in the Territory, among whom rates of decline in the 25–64 age group are considerably lower.

- Cardiovascular disease death rates are higher than the national average in the Northern Territory (20% higher in males and 15% higher in females) and in Tasmania (12% and 10%). Rates are lower than the national average in the Australian Capital Territory (8% lower in males) and Western Australia (6% in males and 7% in females).
- Rates of decline for cardiovascular disease are generally around 3% per year or more except for the Northern Territory where rates of decline are slower.
- Death rates for ischaemic heart disease are highest in Tasmania (9% higher than the national average for males and 5% for females) and Queensland (5% and 7% respectively). Death rates in the Northern Territory and the Australian Capital Territory are about 10% below the national average. Again, rates of decline are slower in the Northern Territory.
- Death rates from cerebrovascular disease are highest in the Northern Territory and Tasmania, and are declining in every State and Territory, except the Northern Territory, where mortality rates are increasing for males and females.

## Indigenous people and other Australians

Indigenous people clearly experience greater death rates for cardiovascular disease than other Australians, but female death rates are falling in both populations.

- Cardiovascular disease death rates are six times higher for Indigenous males and nine times higher for Indigenous females for the 25–64 age group, compared with other Australians.
- The greatest difference in cardiovascular disease death rates between the Indigenous and non-Indigenous populations occurs in the younger age groups.
- Among the Indigenous population, cardiovascular mortality is declining at the rate of 5.2% for females over the period 1991–1996, while for males there is no change.

## **Urban, rural and remote areas**

There have been no marked differentials in cardiovascular mortality between people living in the urban, rural and remote areas of Australia.

- Death rates from cardiovascular disease are slightly higher in rural and remote areas for males but not for females.
- Declines in cardiovascular mortality between 1986 and 1996 are comparable for urban, rural and remote areas.

# Introduction

Cardiovascular disease is one of five National Health Priority Areas (the others are injury, mental health, cancer and diabetes) agreed to at a meeting of Australian Health Ministers in July 1996. Cardiovascular disease comprises all diseases of the circulatory system, including heart disease, stroke and vascular diseases. Its inclusion as a priority area is continued recognition of the massive impact cardiovascular disease has in Australia in terms of burden of illness and economic costs and in terms of the need for coordinated activity to reduce these effects. This report is produced from the national monitoring system established to monitor this disease and its impact. Previous mortality surveillance reports in the Cardiovascular Disease Series are listed in the *Related publications* section at the end of this report.

## The National Cardiovascular Monitoring System

The system comprises the National Centre for Monitoring Cardiovascular Disease, an Advisory Committee, and a number of collaborative projects with other centres.

The National Centre is located within the Australian Institute of Health and Welfare and commenced operation in January 1996. It monitors trends and inequalities in mortality, morbidity and risk factors, monitors progress towards national goals and targets, promotes standards and develops data systems.

The function of the Advisory Committee is to advise on the development and implementation of the monitoring system, and guide and review the Centre's work program. The committee includes representatives from Commonwealth, State and Territory Health Departments, the National Heart Foundation, medical colleges, and academics with expertise in the fields of cardiovascular disease, data collection and analysis.

The inclusion of collaborative projects with other centres recognises that, for the national monitoring system to be fully effective, it is important that it incorporates the expertise that exists in key agencies and centres of excellence.

The components of the national system relate to primary prevention, risk factors, disease incidence, pre-hospital and emergency care, medical and surgical hospital care, rehabilitation, follow-up care, disease prevalence and functional status, palliative care and death.

## Mortality surveillance

This report addresses one of the important functions of the National Centre: to monitor and report on trends and differentials in cardiovascular mortality. The report provides a detailed statistical profile of death from cardiovascular disease and its major components, for Australia, for each State and Territory, for the Indigenous (Aboriginal and Torres Strait Islander peoples) and non-Indigenous populations, and for urban, rural and remote areas.

## Classification of cause of death

The mortality classification is based upon the International Classification of Diseases, Ninth Revision (ICD-9) (World Health Organization 1977). Where more than one condition is mentioned on the medical certificate of cause of death, one 'underlying cause' is selected from those shown. ICD-9 contains detailed rules for this selection. The following classification of causes of death has been used in this report:

Cause of death	ICD-9 code*
Cardiovascular disease (diseases of the circulatory system):	390–459
Rheumatic heart disease	390–398
Hypertensive disease	401–405
Ischaemic heart disease (coronary heart disease):	410–414
Acute myocardial infarction (heart attack)	410
Other ischaemic (coronary) heart disease	411–414
Heart failure	428
Cerebrovascular disease (stroke)	430–438
Atherosclerosis	440
Peripheral vascular disease	441–444
Other cardiovascular disease (other diseases of the circulatory system)	415–417, 420–427, 429, 446–459
All causes	001–999

\*The ICD-9 coding system was first used in Australia in 1979.

## Mortality profiles

Mortality profiles are provided for each cardiovascular disease, where numbers permit.

A full mortality profile for a particular cause of death consists of:

- number of deaths by year, age group and sex;
- age-specific death rates by year, age group and sex;
- crude and age-standardised death rates by year and sex, for all ages and the age group 25–74;
- annual rates of change (with indicators of statistical significance); and
- differences between the most recent death rate and that expected based on projections for that year (with indicators of statistical significance).

The methods used for estimating death rates, annual rates of change, and tests of statistical significance are described in *Appendix A*.

Full mortality profiles and a graph depicting the age-standardised death rates (all ages) and their underlying trend are included for all cardiovascular disease groups at national level, and for the more common disease groups at State and Territory; Indigenous and non-Indigenous; and urban, rural and remote levels. Mortality profiles for the less common causes of death are available on the Australian Institute of Health and Welfare World Wide Web site at <http://www.aihw.gov.au>. Users without Internet access may request the tables on disk.

Full mortality profiles are given when there are at least 16 deaths in any age-specific group, in any year 1985–1996, for either males or females<sup>1</sup>. When this criterion is not satisfied the total number of deaths is given by year and sex, in place of a full mortality profile.

Data sources, terms and concepts are explained more fully in the following sections.

## Death registration data

Registration of deaths in Australia is the responsibility of the State and Territory Registrars of Births, Deaths and Marriages. Information on the cause of death is supplied by the medical practitioner certifying the death or by a coroner. Other information about the deceased is supplied by a relative or other person acquainted with the deceased, or by an official of the institution where the death occurred. The information is provided by the Registrars to the Australian Bureau of Statistics for coding of cause of death and compilation into aggregate statistics. The data in this publication are provided to the Australian Institute of Health and Welfare by the State and Territory Registrars after processing by the Australian Bureau of Statistics.

## Scope and coverage

### National, State and Territory

Registration of deaths is a legal requirement in Australia and is virtually complete. All deaths which occur in Australia are within the scope of the collection, with the exception of deaths of foreign diplomatic personnel.

In the interest of timeliness, the mortality statistics in this publication relate to the year of registration of death. Usually about 5–6% of all deaths (and deaths from cardiovascular disease) which occur in one year are not registered until the following year or later. For national and State and Territory statistics this effect is minimal as the proportion of deaths not registered in the year of occurrence is fairly constant from year to year.

---

1. Although such a decision includes an element of subjectivity, the relative standard error on a count of 16 deaths is 25% (assuming a Poisson distribution for the number of deaths), which is a reasonable compromise between the need for precision and the desire to report in as much detail as possible.

This report covers the period from 1985–1996 for national and State and Territory data, the latest year for which data are available. In 1984 there were abnormal delays in the registration process in New South Wales which had the effect of displacing approximately 2,000 death registrations from 1984–1985. In 1985, these represent about 1.7% of all deaths in Australia and 4.5% of deaths in New South Wales. The effect on estimates of trend for that State is negligible. In 1988 legislation revisions in the Northern Territory meant that some deaths were registered in that year which may not have been registered until 1989 under the former legislation. The effect is negligible for Australia but contributed to the relatively higher cardiovascular death rate for females in the Northern Territory in 1988.

Age-standardised death rates in the Northern Territory and the Australian Capital Territory show greater variation from year to year than the States due to their smaller population base. For reliability the death rates for the Northern Territory and the Australian Capital Territory are averaged over three years (1994–1996) in the *Overview of current trends* section of this report. For the States, death rates are presented for the most recent year, 1996.

### **Indigenous population**

At present there is considerable variation in the quality of data on Indigenous deaths from State to State. Only mortality data for Western Australia, South Australia, the Northern Territory and the Australian Capital Territory are considered to be of sufficient quality for publication, with registration of Indigenous deaths estimated to be over 90% complete in these States and Territories. Due to the small number of deaths and the short period that death data has been collected in the Australian Capital Territory, data from Western Australia, South Australia and the Northern Territory form the basis of Indigenous analysis in this report. For comparability the non-Indigenous section of this report also includes data from only Western Australia, South Australia and the Northern Territory.

Among the Indigenous population the proportion of deaths not registered in the year of occurrence varies by year and State and Territory and is generally in the vicinity of 10–20%, and is sometimes even higher (Anderson et. al 1996). An analysis of Indigenous mortality by year of registration could therefore be misleading, and year of occurrence of death has been used instead. An adjustment was made for deaths that occurred in 1996 that were not registered in that year. The adjustment was based on the proportion of deaths occurring in 1995 but registered in 1996. The additional deaths were spread across age groups and causes of death in proportion to the number actually recorded. For comparability, the non-Indigenous mortality profiles were also based on year of occurrence with an adjustment factor for the most recent year. For the Indigenous population, mortality trends have been examined for the period 1991–1996. Between 1991 and 1996 there was a large increase in the number of Indigenous people counted in the Population Census, to an extent greater than can be explained by natural increase. The number of Indigenous people identified in the 1996 Census was about 17% higher than previously published projections for 1996 based on the 1991 Census. In this report, Indigenous population estimates for 1992–1996 are based on the 1996 Census.

### **Urban, rural and remote areas**

Urban, rural and remote zones are identified in this report using the Rural, Remote and Metropolitan Areas (RRMA) classification (DPIE & DHSH 1994). The RRMA classification assigns each Statistical Local Area (SLA) into one of seven categories which can be re-grouped into three larger zones or areas: urban (metropolitan), rural and remote. The classification takes into account population numbers and an index of remoteness. The three zones or areas are defined as follows:

- Urban zone
  - Capital cities
  - Other metropolitan centres (urban centre population  $\geq 100,000$ )
- Rural zone (index of remoteness  $< 10.5$ )
  - Large rural centres (urban centre population 25,000–99,000)
  - Small rural centres (urban centre population 10,000–24,999)
  - Other rural areas (urban centre population  $< 10,000$ )

- Remote zone (index of remoteness > 10.5)
  - Remote centres (urban centre population  $\geq 5,000$ )
  - Other remote areas (urban centre population  $< 5,000$ ).

SLA boundaries may be re-drawn between censuses, and at each census, area classifications and their population counts are updated.

This report examines mortality trends for the three larger areas (urban, rural and remote), as numbers of deaths can become too small for accurate trend estimation in the seven-category classification. Year of registration of death has been used in examining the urban, rural and remote statistics in this publication. The analysis is for the period 1986–1996 as population estimates at RRMA level are not available prior to 1986.

## **Age groups**

In this report results are given for males and females separately, and for the ten age groups <25, 25–34, 35–44, 45–54, 55–59, 60–64, 65–69, 70–74, 75–84, and 85+. Results are also given for the age group 25–74. This age range aligns with National Health Priority Area indicators for cardiovascular mortality.

However for the Indigenous population a slightly different age grouping has been used (25–64 and age groups: <25, 25–34, 35–44, 45–54, 55–64, 65–74, 75+), reflecting the lower life expectancy of the Indigenous population (15–20 years younger than their Australian counterparts).

## **Data quality**

The Australian Bureau of Statistics uses a variety of quality control measures to ensure mortality data are as reliable as possible. When a medical certificate of cause of death does not give sufficient information to enable accurate coding of the underlying cause of death, and the deceased was aged less than 75, the Australian Bureau of Statistics writes to the certifying doctor (or medical superintendent when death occurred in a hospital) seeking additional information. When the deceased was aged 75 or over, queries are made only where an operation has been performed but the condition requiring surgery was not stated. Responses are returned via the Registrar of Births, Deaths and Marriages, who supplies the original information. Other quality control measures include check-coding of cause of death, detailed computer editing of data, and checks on the statistical output, at the individual record and aggregate levels.

Since 1993, the Queensland office of the Australian Bureau of Statistics has been responsible for processing all of Australia's cause of death data to ensure greater consistency in coding and improved data quality. Before this, cause of death processing was carried out in each of the Australian Bureau of Statistics offices. As of 1 January 1997 the Australian Bureau of Statistics has introduced a new automatic coding software, which identifies multiple causes of deaths within Australia.

It has been demonstrated that coding of death for acute myocardial infarction (ICD-9 410) and ischaemic heart disease (ICD-9 410–414) is quite accurate in Australia (Boyle & Dobson 1995).

# Overview of current trends

## Australia

### Cardiovascular disease (or diseases of the circulatory system)

Cardiovascular disease was the leading cause of death among Australians in 1996, accounting for 53,990 deaths or 42% of deaths from all causes (Table 1). Males were more likely to die from cardiovascular diseases than were females across almost all age groups, the exception being the 85 and over age group, where twice as many females died from cardiovascular diseases in 1996 than did males.

While cardiovascular disease remains Australia's greatest health problem there have been significant improvements in cardiovascular death rates in recent decades. The peak occurred in 1968 and since then death rates from cardiovascular disease have declined by over 60% among males and females.

Current annual rates of decline of cardiovascular mortality are 3.7% for males and 3.6% for females (Table 1). The decline in cardiovascular mortality has been occurring at all ages, with the greatest annual rate of decline among males and females aged between 45 and 59 (over 6%) (Figure 1). The decline in cardiovascular mortality has been more rapid than that for total mortality that is declining at a rate of 2.2% among males and 1.9% among females (Table 1).

**Table 1: Proportion of cardiovascular deaths in 1996, and annual rate of change in the age-standardised death rate (all ages), 1985–1996**

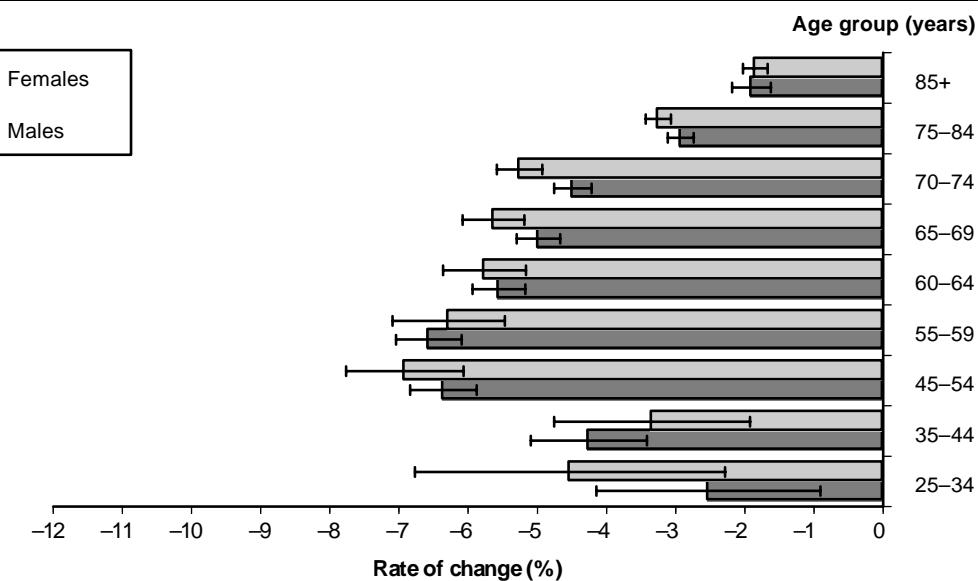

Sub-category	Males			Females		
	Proportion of CVD*	Annual rate of change (%)	95% confidence limits	Proportion of CVD (%)	Annual rate of change (%)	95% confidence limits

<b>Cardiovascular disease (N)</b>	<b>26,550</b>	<b>-3.7</b>	<b>-3.8, -3.6</b>	<b>27,440</b>	<b>-3.6</b>	<b>-3.7, -3.5</b>
<i>All causes</i>	68,206	-2.2	-2.2, -2.1	60,513	-1.9	-2.0, -1.9

\* Cardiovascular disease

Australia has the ninth lowest death rate from cardiovascular disease out of the 29 OECD countries. However, given that Australian death rates are 71% higher than for Hong Kong (for males) and 55% higher than for France (for females), this indicates the potential for further reductions in the cardiovascular mortality rate in Australia (AIHW 1998).

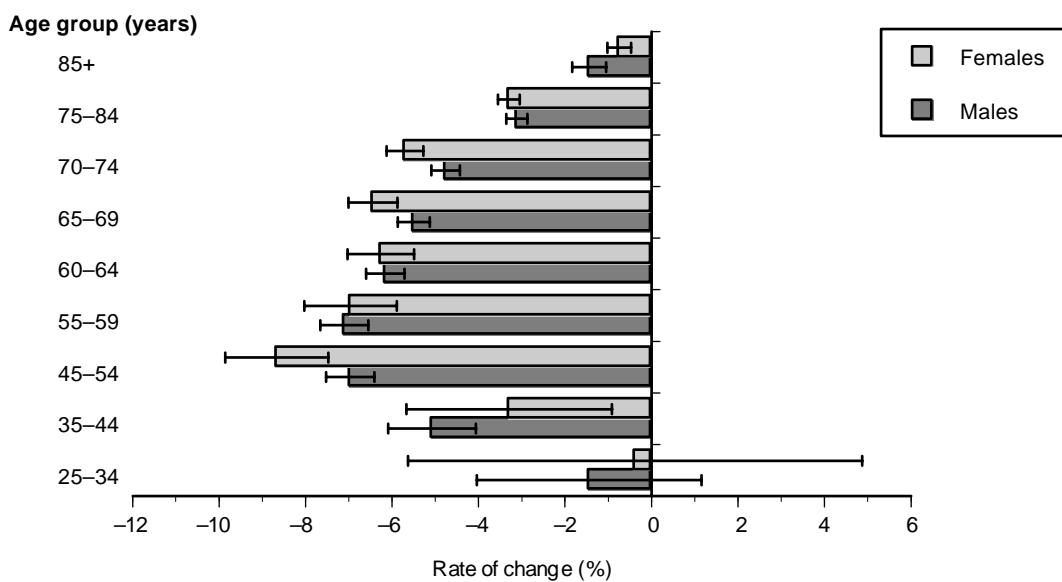

### Ischaemic heart disease (or coronary heart disease)

Ischaemic heart disease was the major cardiovascular cause of death, representing 55% of all such deaths. Mortality from ischaemic heart disease has continued the decline that began in the 1960s and is currently declining at a rate of 4% per year among males and 3.6% per year among females. Rates of decline have been greatest among the 45–54 age group, 7% per year among males and 9% per year among females (Figure 2).

Note: Bars represent 95% confidence interval on the estimated rate of change.

**Figure 1: Cardiovascular disease; annual rate of change in age-specific death rates, 1985–1996**

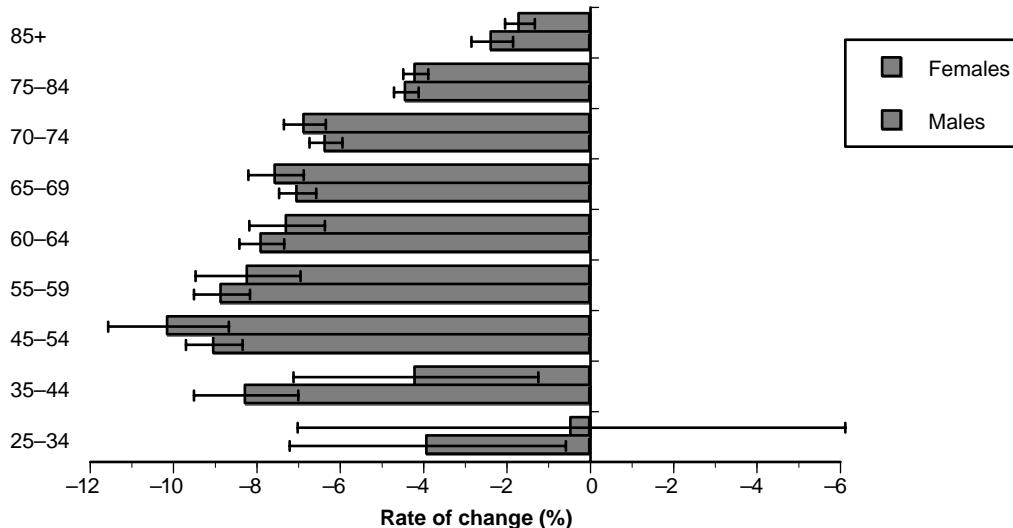

Note: Bars represent 95% confidence interval on the estimated rate of change.

**Figure 2: Ischaemic heart disease; annual rate of change in age-specific death rates, 1985–1996**

### Acute myocardial infarction (or heart attack)

Mortality from acute myocardial infarction, the major contributor to ischaemic heart disease mortality (60% of such deaths), has been declining slightly faster than ischaemic heart disease at an annual rate of 5.5% among males and 4.7% among females.

The differential in rates of decline between the sexes was highest in the 35–44 age group, where the male rate of decline was twice that of the female rate of decline. There were significant rates of decline at all ages, but the rates were greatest among females aged 45–54 (10%) and males aged 45–59 (9%) (Figure 3).

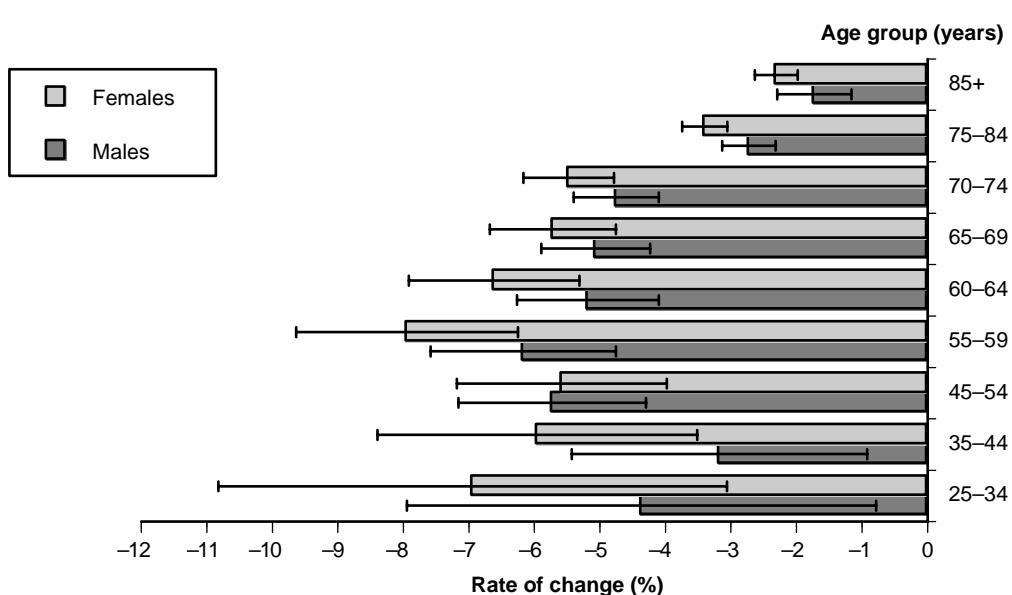

**Age group (years)**

Note: Bars represent 95% confidence interval on the estimated rate of change.

**Figure 3: Acute myocardial infarction; annual rate of change in age-specific death rates, 1985–1996**

**Cerebrovascular disease (or stroke)**

Mortality from cerebrovascular disease, the second leading cardiovascular cause of death (contributing 24% of cardiovascular deaths) has been declining at a rate of 3.4% among males and 3.8% among females. The largest sex differentials in rates of decline occurred in the 35-44 age group, where the female rate of decline was almost twice that of the male rate (6% compared to 3.2%). Rates of decline were highest for the 55-59 age group (6.2% for males and 7.9% for females), with lower rates of decline with increasing age (Figure 4).

Note: Bars represent 95% confidence interval on the estimated rate of change.

**Figure 4: Cerebrovascular disease; annual rate of change in age-specific death rates, 1985–1996**

## Other cardiovascular diseases

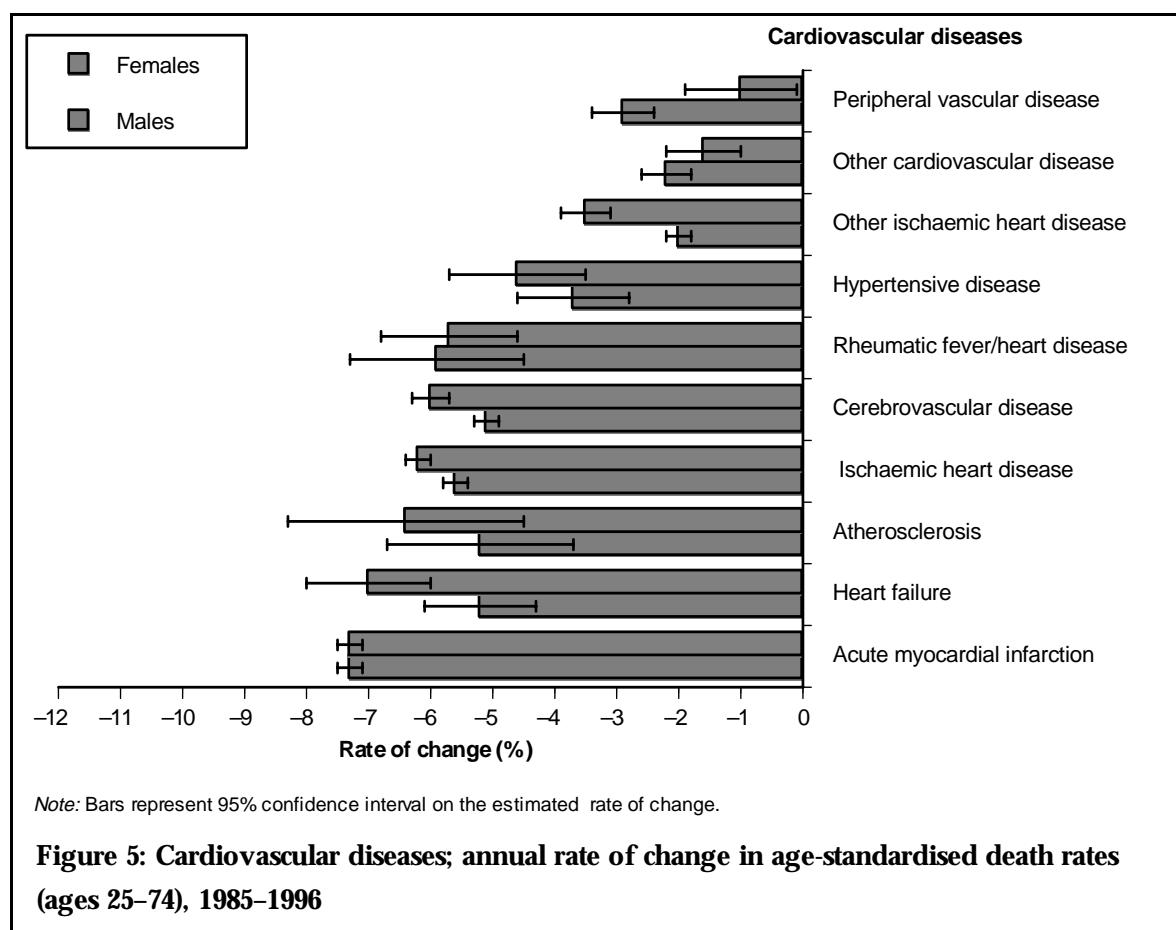

Mortality from heart failure, peripheral vascular disease, hypertensive disease, and rheumatic heart disease were also declining, with rates of decline slowest for peripheral vascular disease (2.1% among males and 0.6% among females). Death rates attributed to atherosclerosis were declining at a faster rate per year than any of the other cardiovascular diseases (7.8% and 9.1% among males and females respectively), with rates of decline higher in older age groups.

## National targets for cardiovascular disease

The report *Better Health Outcomes for Australians* recommends that national targets for premature mortality (25–74 years) from ischaemic heart disease be set at 1,100 deaths per million population among males and 400 deaths per million population among females, for the year 2000. In 1985 age-standardised death rates from ischaemic heart disease (for the 25–74 age group) were 2,661 and 991 deaths per million population for males and females respectively. By 1996 these rates had declined to 1,415 and 495 deaths per million population. If the current rates of decline continue these rates will decrease further by the year 2000 to 1,122 deaths per million population among males and 397 among females.

## Age group 25–74

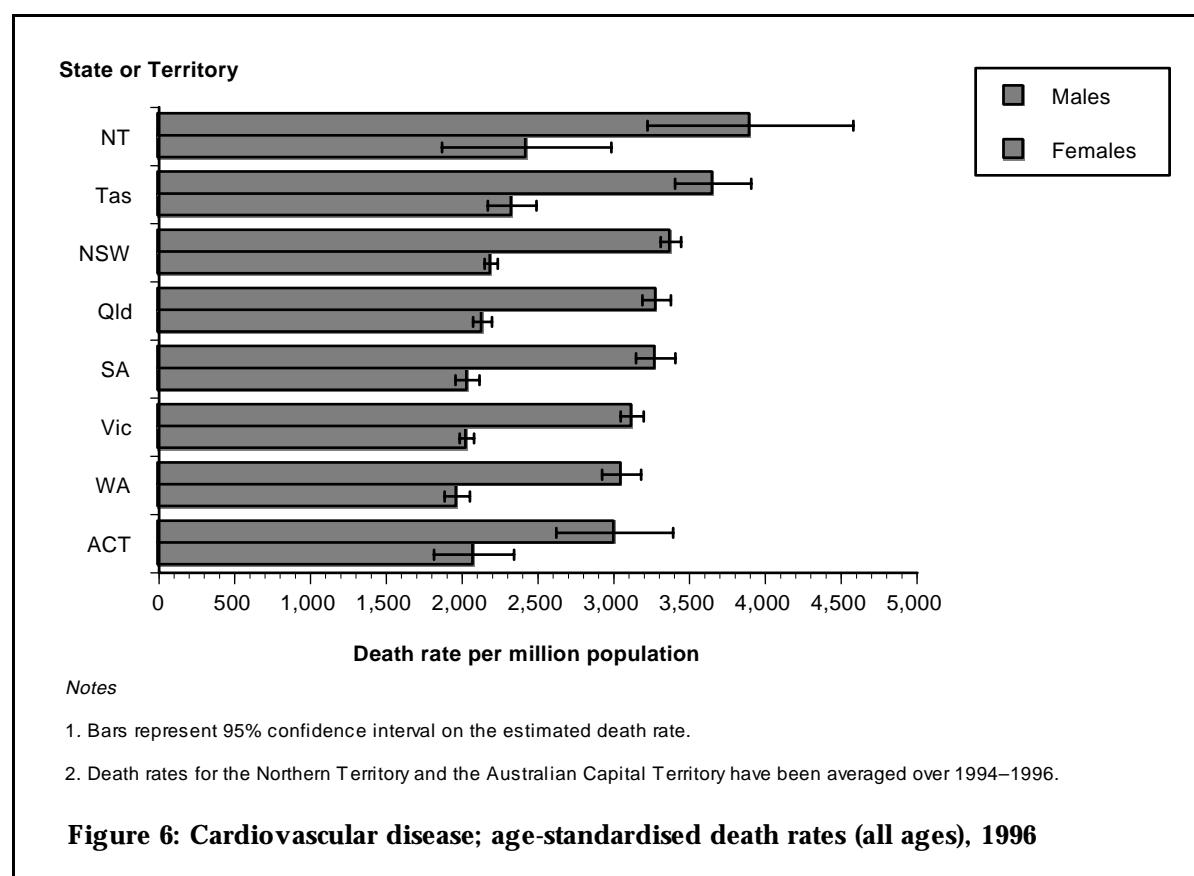

Annual rates of decline for each cardiovascular disease were generally greater for the 25–74 age group than that for all ages, reflecting the slower declines in mortality among the very old. Among those aged 25–74 most cardiovascular diseases were declining by at least 5% per year among males and females (Figure 5). For the 25–74 age group mortality from cardiovascular diseases as a proportion of all causes was significantly lower than that for all ages (31% compared to 42%). For further details see the detailed mortality profiles for Australia.

## States and Territories

### Cardiovascular disease

Mortality from all cardiovascular diseases was highest in the Northern Territory at 3,900 and 2,426 deaths per million population for males and females respectively in 1994–96<sup>2</sup>. This high mortality rate in the Northern Territory can mainly be attributed to the relatively large proportion of Indigenous people in the Territory (26%) compared to the rest of Australia (less than 3%), among whom death rates are two times higher than for other Australians (discussed in more detail in the *Indigenous population* section of this report). Of the remaining States and Territories, death rates were highest in Tasmania and lowest in the Australian Capital Territory for males and Western Australia for females (Figure 6).

The Australian trend of decreasing cardiovascular mortality and higher rates of decline from cardiovascular disease than from all causes, remained consistent across all the States and Territories (Table 2). New South Wales had the largest rate of decline among males (4%) and Tasmania the largest among females (3.9%), with rates of decline also high among males in Victoria and females in New South Wales. The Northern Territory had the lowest rate of decline from cardiovascular mortality among both males and females (0.7% and 2.1% respectively). This slower rate of decline is mainly attributed to the relatively large proportion of Indigenous people in the Territory (26% compared to less than 3% elsewhere), among whom rates of decline in the 25–64 age group are considerably lower. Death rates among Indigenous people in the Northern Territory are declining at a slower rate than among

2. For reliability, death rates in the Northern Territory and the Australian Capital Territory have been averaged over three years (1994–1996). For the States, death rates relate to the most recent year, 1996. For further details see *Introduction*.

Indigenous people in Western Australia, South Australia and the Northern Territory combined (see the *Indigenous population* section). Differences in mortality among Indigenous people living in the Northern Territory compared with those living in Western Australia and South Australia may reflect the diversity of Australia's Indigenous population (ATSIHWIU 1997).

**Table 2: Selected cardiovascular diseases and all causes; annual rate of change in age-standardised death rates (all ages), 1985–1996 (%)**

Note: 95% confidence limits for annual rates of change are all within 0.2 of the estimated rate.

### Ischaemic heart disease

Mortality from ischaemic heart disease for both males and females was highest in Tasmania and Queensland, followed by New South Wales. The Australian Capital Territory and the Northern Territory had the lowest death rates for males and females in 1994–1996 (Figure 7). The Northern Territory has moved from having the highest overall death rate from cardiovascular diseases to the lowest for ischaemic heart disease. This may be attributable to the distribution of cardiovascular deaths in the Northern Territory. Ischaemic heart disease accounted for a lower proportion of cardiovascular deaths in the Northern Territory (43%) than in the other States and Territories (55%), due mainly to high mortality from other causes such as other cardiovascular diseases<sup>3</sup> (15% of deaths in the Northern Territory compared to 8% elsewhere).

Rates of decline in ischaemic heart disease mortality were again slowest in the Northern Territory, decreasing at a rate of 1.5% per year for males and 2.7% per year for females. For the remaining States and Territories rates of decline were largest in New South Wales (4.4% for males and 3.8% for females) followed by Tasmania (Table 2).

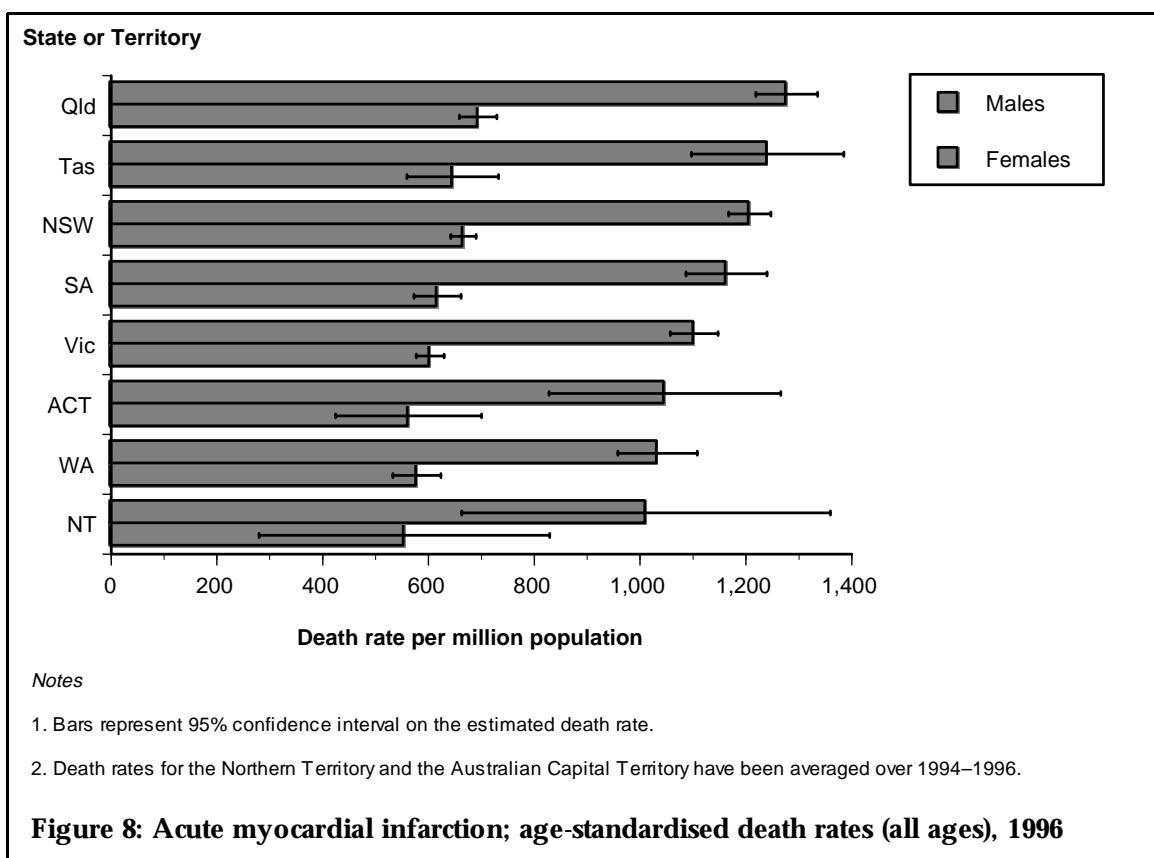

3. Includes such diseases as pulmonary circulation, other forms of heart disease, diseases of the arteries, arterioles and capillaries, and diseases of veins and lymphatics, and other diseases of the circulatory system.

### Acute myocardial infarction

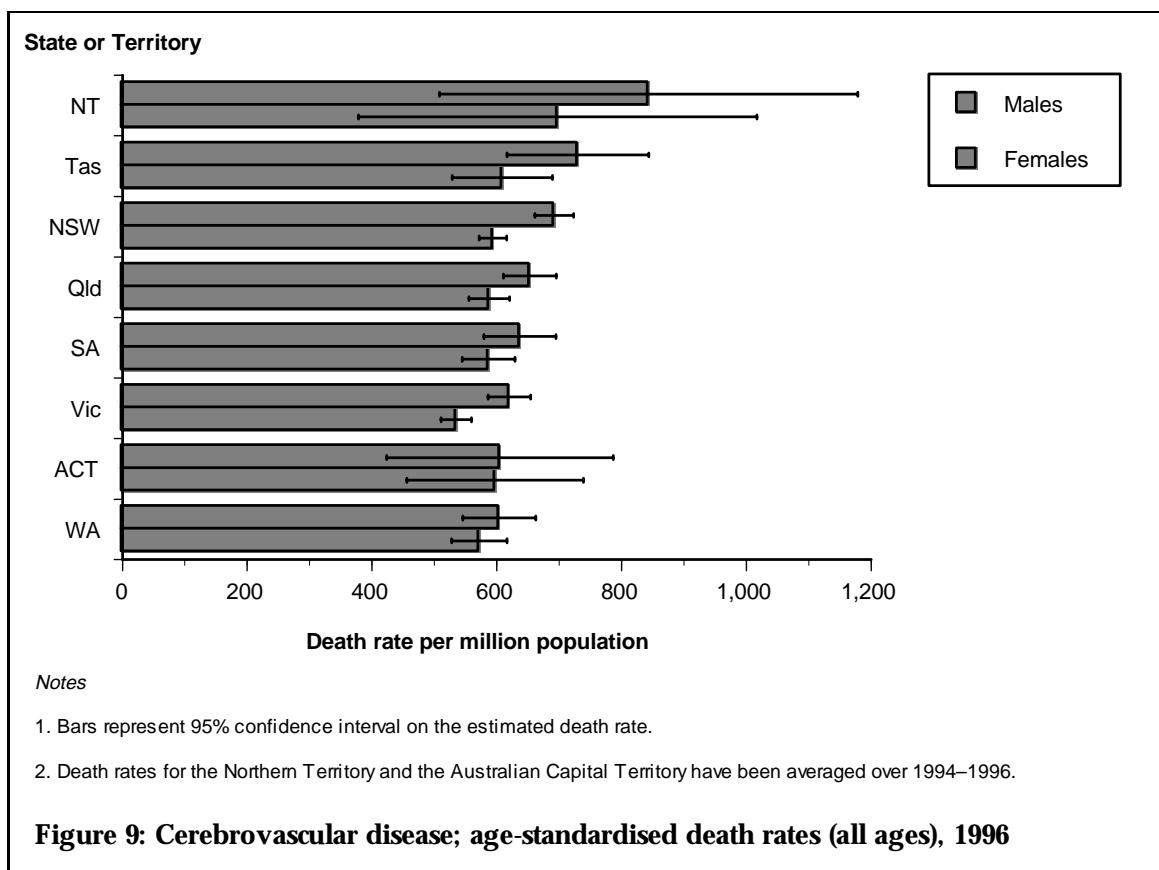

Death rates attributed to acute myocardial infarction were highest in Queensland (1,277 and 694 deaths per million population for males and females respectively) and lowest in the Northern Territory (Figure 8). The Northern Territory had a lower proportion of cardiovascular deaths from acute myocardial infarction than the rest of Australia (24% compared with 33%).

Mortality from acute myocardial infarction was declining at a faster rate than for ischaemic heart disease overall, with the greatest rate of decline occurring in Western Australia (6.1% for males and 5.2% for females). Rates of decline were also high in New South Wales and South Australia, while the lowest rates of decline were seen in the Northern Territory (1.4% and 3.3% respectively for males and females) (Table 2).

### Cerebrovascular disease

The Northern Territory had the highest death rate from cerebrovascular disease in 1994–1996 and was the only State or Territory where death rates increased over the period 1985–1996. The rate of increase was 0.4% per year for males and 3.8% per year for females. Mortality from cerebrovascular disease was also high in Tasmania and New South Wales and lowest in Western Australia for males and Victoria for females. Rates of decline among males was greatest in New South Wales (4.1% per year), while among females Tasmania had the greatest rate of decline of 4.5% per year (Figure 9 and Table 2).

## Projections for the year 2000

In the year 2000, based on current rates of decline, death rates for ischaemic heart disease between ages 25–74 will continue to be lowest in the Australian Capital Territory, Victoria and Western Australia and highest in the Northern Territory, South Australia (for males), Tasmania (for females) and Queensland (Table 3).

**Table 3: Year 2000 projections\* for ischaemic heart disease; age-standardised death rates and 95% confidence intervals (25–74)**

State and Territory	Males		Females	
	Rate	95% Confidence limit	Rate	95% Confidence limit
New South Wales	1,112	1,098–1,126	413	405–422
Victoria	1,041	1,028–1,055	352	344–359
Queensland	1,206	1,191–1,221	435	426–444
Western Australia	1,098	1,084–1,112	373	365–381
South Australia	1,238	1,223–1,253	382	374–390
Tasmania	1,194	1,180–1,209	488	478–497
Australian Capital Territory	912	899–925	276	269–283
Northern Territory	1,478	1,461–1,496	938	922–954
<b>Australia</b>	<b>1,122</b>	<b>1,108–1,137</b>	<b>397</b>	<b>389–405</b>

\* The projected age-standardised death rates for the year 2000 have been calculated using a Poisson regression model.

## **Indigenous population**

The identification of Indigenous people is not accurately recorded in death registrations in all States and Territories, which means that a reliable national picture of Indigenous mortality cannot be obtained. Since 1993 identification of Indigenous people on death records in Western Australia, South Australia and the Northern Territory has been of an acceptable quality, with registration of Indigenous deaths estimated to be over 90% complete in these jurisdictions (ABS 1993). The information from these States and Territory has been combined to produce quasi-national estimates of death rates for the Indigenous population. For comparability the non-Indigenous estimates also include data from only Western Australia, South Australia and the Northern Territory.

The number of people who identified themselves as Indigenous in the 1996 Census was about a third higher than the number who did so in 1991, a difference much larger than can be explained by natural increase (Cunningham 1998). These changes in Indigenous identification make interpretation of long-term trends difficult. In this report, population estimates for 1992–1996 are based on the 1996 Census, while the 1991 estimate is taken from the 1991 Census. By examining data over a relatively short time period (1991–1996), this lessens the impact of changes in Indigenous identification.

Over the period 1991–1996, mortality has been declining among Indigenous females at a rate of 3.1% per year, but increasing slightly among Indigenous males (0.9%). This equates to 2,923 and 2,217 deaths among Indigenous males and females respectively between 1991 and 1996. Indigenous Australians had higher rates of death than non-Indigenous Australians for most cardiovascular causes of death. Obesity and smoking are more prevalent among Indigenous people than other Australians, which places them at a greater risk of developing health problems such as heart disease (AIHW 1998; Cunningham 1997; Cunningham & Mackerras 1998).

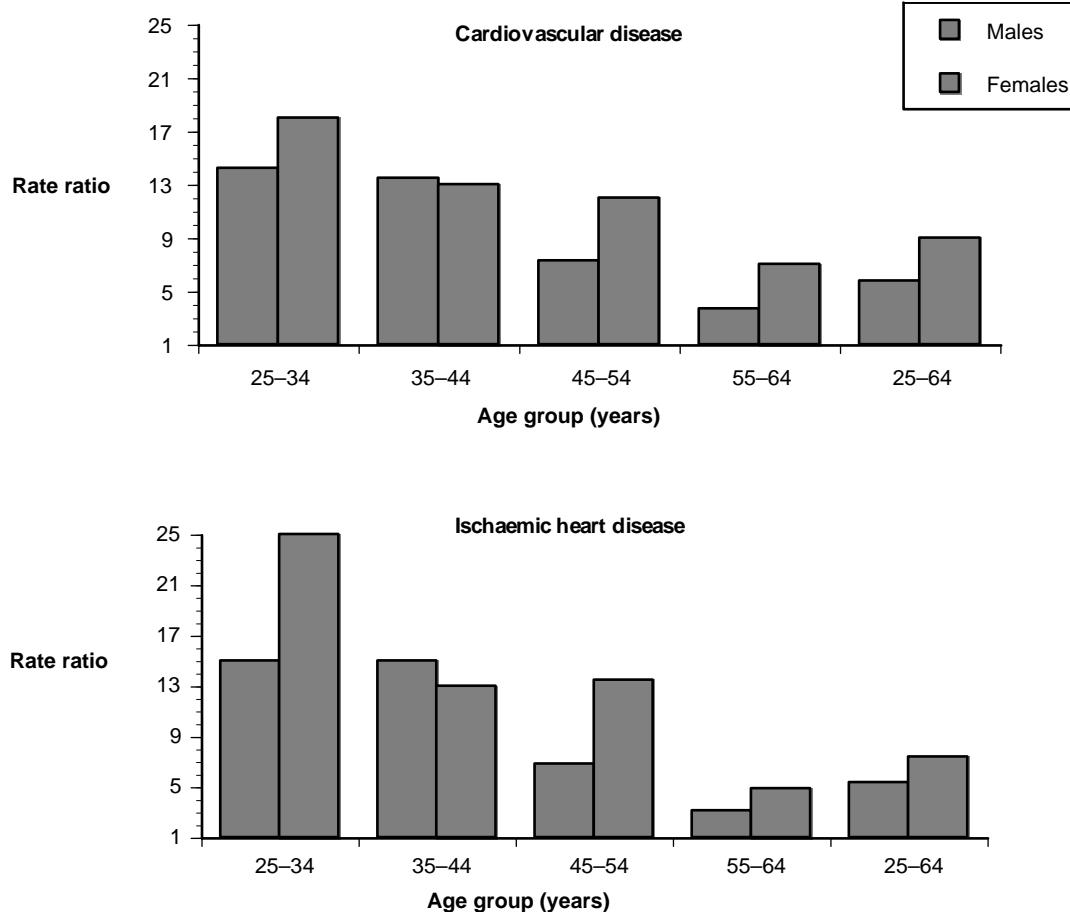

## **Cardiovascular disease**

Over the period 1994–1996 cardiovascular diseases accounted for 28% of all deaths of Indigenous people, a significantly lower proportion than that evident among the non-Indigenous population (42%). However, mortality from diabetes, road traffic accidents and respiratory diseases constituted a higher proportion of all deaths for Indigenous people, compared with other Australians, with these proportions about two to three times higher among the Indigenous population (ABS 1997).

While cardiovascular diseases comprised a smaller proportion of all deaths among the Indigenous population compared with other Australians, the age-standardised cardiovascular disease death rates for Indigenous people in 1994–1996 were two times greater than non-Indigenous rates. This ratio was greater among adults of working age (25–64), for whom Indigenous people had six and nine times the cardiovascular death rate for non-Indigenous males and females respectively. The difference in rates between the Indigenous and non-Indigenous populations was greater in relative terms for females than for males across almost all age groups. In fact, the death rates were greater at all ages for the Indigenous population compared to other Australians, with the greatest difference in relative terms occurring in the younger age groups (Figure 10).

Mortality from cardiovascular disease among the Indigenous population has been declining at a rate of 5.2% for females, while for males there was no statistically significant rate of change over the period 1991–1996. The female rate of decline is a recent shift, with previous published data pointing to an increase in cardiovascular mortality of 2% for females between 1985 and 1994 (Anderson et al. 1996). While caution needs to be taken in interpreting these results due to changes in Indigenous population estimates, it is possible that a new trend may be developing for Indigenous females.

Over the period 1991–1996 the decline in death rates for Indigenous females was considerably greater than among non-Indigenous females (5.2% compared to 2.6%). For males, the pattern was not so clear with mortality declining by 3.1% per year among the non-Indigenous population, while among the Indigenous population there was no significant rate of change over the period (Figure 11). For the 25–64 age group, however, mortality among Indigenous males was declining by 2.5% per year, a slower rate than that for the corresponding non-Indigenous population (4.6%).

Note: Rate ratio = Indigenous rate divided by non-Indigenous rate. A ratio of 1 indicates no difference. Ratios greater than 1 indicate higher rates among Indigenous people than non-Indigenous people.

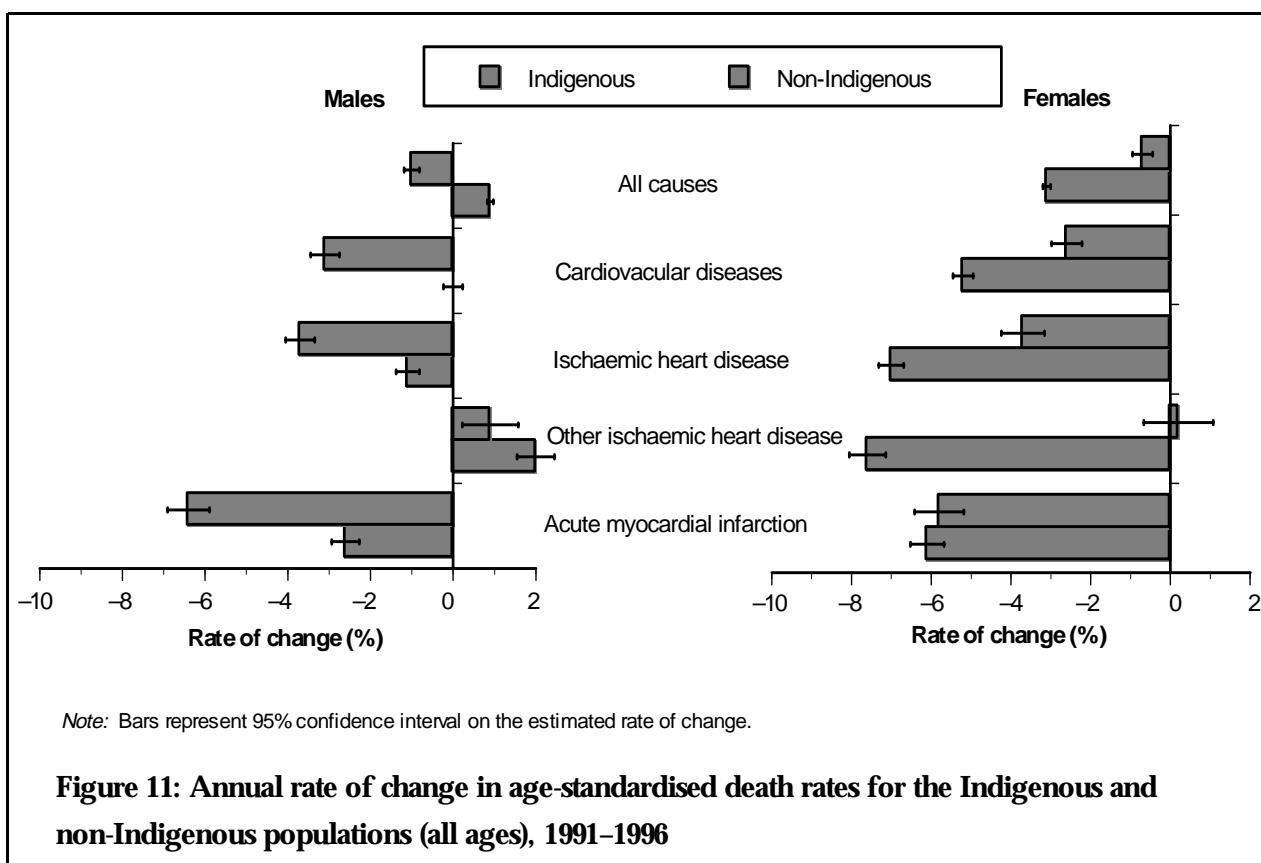

**Figure 10: Cardiovascular disease and ischaemic heart disease; ratios of age-specific death rates for the Indigenous and non-Indigenous populations (25–64), 1994–96**

### Ischaemic heart disease

Ischaemic heart disease remained the leading contributor to mortality from cardiovascular diseases for Indigenous people, 55% among males and 41% among females in 1994–1996. Mortality from this cause was declining at a rate of 1.1% per year among Indigenous males, a slower rate than that for non-Indigenous males (3.7%). For females, however, Indigenous death rates declined at a greater rate than non-Indigenous death rates (7% compared to 3.7%) over the period 1991–1996 (Figure 11).

National targets for the Indigenous population endorsed by the Australian Health Ministers Advisory Committee are set at reducing mortality from ischaemic heart disease by 50% in 10 years. Based on current rates of decline, Indigenous females, with rates of decline of 7% per year, are achieving the national target, while Indigenous males (annual decline of 1.1%) are not.

Death rates from ischaemic heart disease for the Indigenous population in 1994–1996 were 1.6 times greater than for other Australians. For the 25–64 age group the difference was even more pronounced, with Indigenous males and females having five and seven times the expected death rate of their non-Indigenous counterparts. The greatest difference between the Indigenous and non-Indigenous populations occurred in the younger age groups (Figure 10).

### Acute myocardial infarction

Between 1991 and 1996 mortality from acute myocardial infarction for Indigenous males was declining slightly faster than for ischaemic heart disease at a rate of 2.6%. Rates of decline were considerably slower among Indigenous males (2.6%) compared with non-Indigenous males (6.4%). For females, rates of decline were similar for the Indigenous and non-Indigenous populations, although slightly higher among the Indigenous population, 6.1% compared to 5.8% (Figure 11).

### Cerebrovascular disease

Mortality from cerebrovascular disease among the Indigenous population is relatively small. Between 1991 and 1996 there were only 150 and 154 deaths from cerebrovascular disease identified in Indigenous males and females respectively. Due to the small number of deaths in each of the age-specific groups no accurate trend analysis can be undertaken for this cause of death.

## Urban, rural and remote areas

### Cardiovascular disease

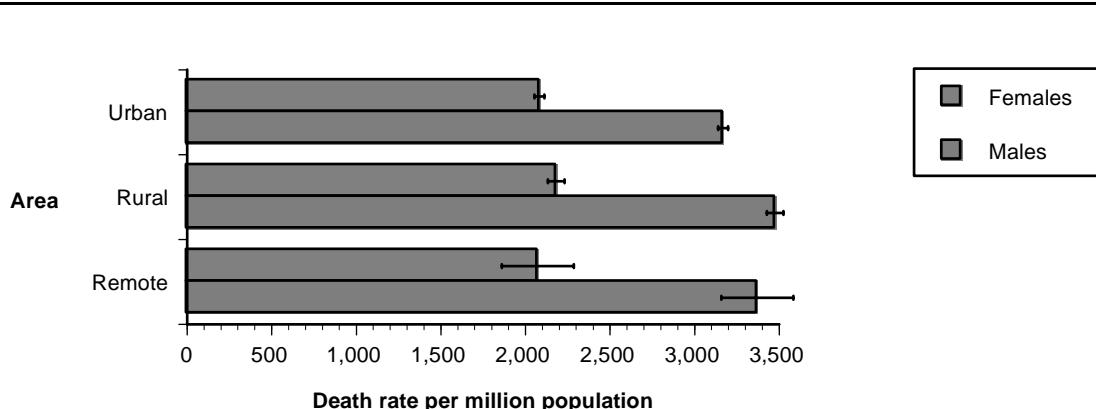

Mortality differences between urban, rural and remote areas are influenced by the proportion of Indigenous people in each area. While the proportion of Indigenous people in urban and rural areas is too small to influence their mortality rates, the relatively high concentration in remote areas (18%) could have a considerable impact on differentials between remote and other areas. Mortality differentials between areas may also reflect differences in access to, and use of, health services. Knowledge of, and attitudes to, illness could also be contributory factors, as could socioeconomic factors.

For males, death rates from cardiovascular disease tended to be slightly higher in rural and remote areas than in urban areas, largely due to ischaemic heart disease (Table 4 and Figure 12). For females, cardiovascular death rates showed little difference across these areas.

**Table 4: Selected cardiovascular diseases and all causes; age-standardised death rates and rate ratios for urban, rural and remote areas (all ages), 1996**

	Urban			Rural			Remote		
	Rate	SE (rate)	Ratio	Rate	SE (rate)	Ratio	Rate	SE (rate)	Ratio

<i>All causes</i>	<i>4,942</i>	<i>23.9</i>	<i>1</i>	<i>5,120</i>	<i>39.7</i>	<i>1.04</i>	<i>5,746</i>	<i>176.4</i>	<i>1.17</i>

Note: Ratio = rural or remote rate divided by urban rate. A ratio of 1 indicates no difference from urban areas. Ratios greater than 1 indicate higher rates among rural and remote areas compared with urban areas.

Note: Bars represent 95% confidence interval on the estimated death rate.

**Figure 12: Cardiovascular disease; age-standardised death rates (all ages), 1996**

There were no marked differences in rates of decline in cardiovascular mortality across urban, rural and remote areas (Table 5). In all three areas and for both sexes, change was more rapid for cardiovascular mortality than for mortality from all causes (Table 5).

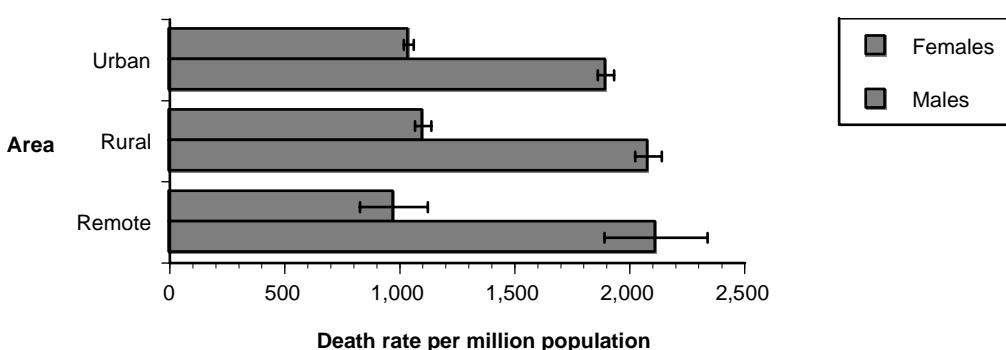

**Table 5: Selected cardiovascular diseases and all causes; annual rate of change in the age-standardised death rate (all ages) in urban, rural and remote areas, 1986–1996**

	Males			Females		
	Urban	Rural	Remote	Urban	Rural	Remote
Ischaemic heart disease	-4.2	-3.5	-3.1	-3.9	-3.2	-3.9
Acute myocardial infarction	-5.8	-5.0	-5.2	-5.1	-4.5	-5.3
Cerebrovascular disease	-3.2	-2.8	-2.9	-3.4	-3.4	-3.1
Cardiovascular disease	-3.7	-3.3	-3.0	-3.5	-3.2	-3.7
<b>All causes</b>	<b>-2.2</b>	<b>-1.8</b>	<b>-2.0</b>	<b>-1.6</b>	<b>-1.7</b>	<b>-1.8</b>

Note: All annual rates of change are statistically significant at the 1% level.

### Ischaemic heart disease

Mortality from ischaemic heart disease was 10–11% higher among rural and remote males compared to urban males (Figure 13 and Table 4). There was less variation in the level of ischaemic heart disease mortality among females. The annual rates of change varied slightly across the three areas, 4.2% among urban males to 3.1% among remote males (Table 5). The rates of decline for urban and remote females were similar and slightly higher than for their rural counterparts.

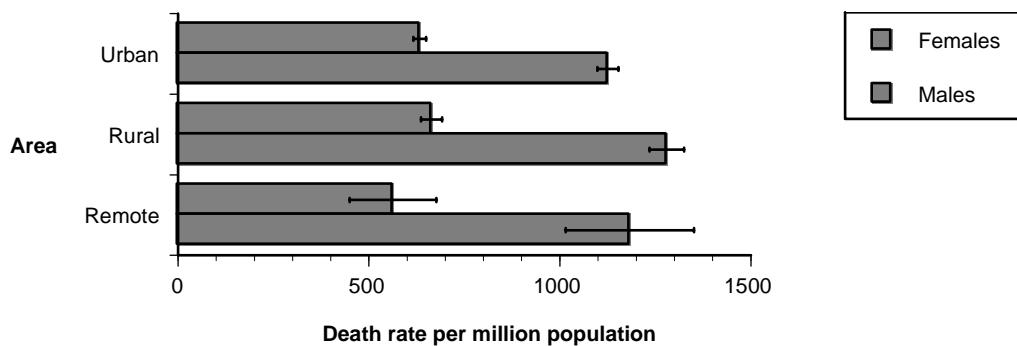

Note: Bars represent 95% confidence interval on the estimated death rate.

**Figure 13: Ischaemic heart disease; age-standardised death rates (all ages), 1996**

### Acute myocardial infarction

Acute myocardial infarction accounted for about 60% of ischaemic heart disease deaths in urban and rural areas, and 57% in remote areas. Mortality attributed to acute myocardial infarction was 14% higher among rural males compared to urban males, and was about 10% lower for remote females compared with their urban counterparts (Figure 14 and Table 4). The mortality rate for acute myocardial infarction declined faster than for ischaemic heart disease. Urban, rural and remote areas all showed a rapid decline, with urban areas in the lead for males (5.8%) and remote areas in the lead for females (5.3%) (Table 5).

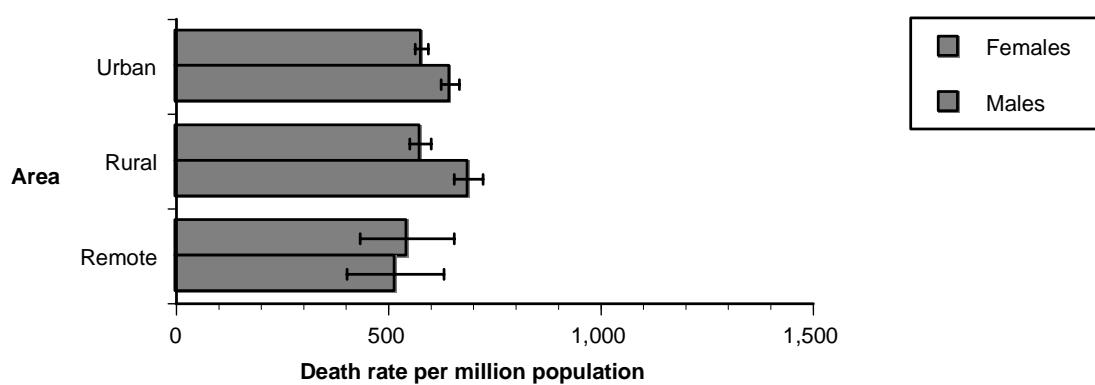

Note: Bars represent 95% confidence interval on the estimated death rate.

**Figure 14: Acute myocardial infarction; age-standardised death rates (all ages), 1996**

### Cerebrovascular disease

In 1996, cerebrovascular disease accounted for a higher proportion of all cardiovascular deaths among females than among males, in all three areas. The cerebrovascular mortality rate was lowest for remote males, 20% lower than for urban males (Figure 15 and Table 4). The mortality rate was highest for rural males. There was virtually no difference across the three areas for females. Cerebrovascular mortality was declining at about 3% per year in all three areas (Table 5).

Note: Bars represent 95% confidence interval on the estimated death rate.

**Figure 15: Cerebrovascular disease; age-standardised death rates (all ages), 1996**

### Age group 25–74

Premature deaths (between ages 25–74) accounted for 41–42% of all cardiovascular deaths among males in both urban and rural areas, and about 57% in remote areas. The proportion varied more among females, from 18% in urban areas and 20% in rural, to 36% in remote areas. In this age range, mortality differentials across the three areas were generally more pronounced than for all ages.

Trend: Estimated annual change (%).

RD: Relative difference between observed and projected rate for 1996, as % of projected value.

Significance level: \*p &lt; 0.05, \*\*p &lt; 0.01.

## Appendix A: Statistical methodology

### Death rates

This report uses three types of mortality indicators. These are age-specific death rates, crude death rates and age-standardised death rates, as described below. All rates are calculated separately for males and females and are expressed per million population. Population data are the estimated resident population at 30 June in each year, published by the Australian Bureau of Statistics<sup>4</sup>.

#### Age-specific death rates

Age-specific death rates are death rates relating specifically to a certain age group. For each age group they have been calculated as the number of deaths in that age group divided by the mid-year estimated resident population for that age group, i.e.

$$r_i = d_i / p_i$$

where  $r_i$  is the age-specific death rate for age group  $i$ ,  $d_i$  is the number of deaths for age group  $i$ , and  $p_i$  is the mid-year estimated resident population for age group  $i$ .

#### Crude death rates

The annual crude death rate is the total number of deaths in a year divided by the total mid-year estimated resident population, i.e.

$$CR = \sum d_i / \sum p_i$$

where  $CR$  is the crude death rate,  $d_i$  is the number of deaths for age group  $i$ , and  $p_i$  is the mid-year estimated resident population for age group  $i$ . The crude death rate does not reflect changes in the age structure of the population over time.

#### Age-standardised death rates

Age-standardisation is a method of adjustment to allow for the effect of variation in the population age structure when comparing death rates for different years or different locations (e.g. between States and Territories). This report has used the 'direct' standardisation method, which applies the age-specific death rates for a particular year to a standard population (Armitage & Berry 1987). This produces an estimate of the death rate which would have prevailed in the standard population if it had experienced the age-specific death rates in the year under study.

The standard population used is the total estimated 1991 mid-year Australian population. The usual convention of using age-specific death rates for five-year age groups, defined as 0–4, 5–9, ..., 80–84, 85+ years, has been followed for the standardisation according to the following formula:

$$ASR = \sum r_i P_i / \sum P_i$$

where  $ASR$  is the age-standardised death rate,  $r_i$  is the age-specific death rate for age group  $i$ , and  $P_i$  is the standard population in age group  $i$ .

### Modelling the data

The underlying annual rate of change from 1985–1996 (or 1991–1996 for the Indigenous population) has been estimated for age-specific and age-standardised death rates. An appropriate model for this type of mortality data is a Poisson regression model, with a Poisson error distribution, a log link function and the natural log of population treated as an 'offset' (Breslow & Day 1987; Brillinger 1986; Valkonen 1989). For a particular cause of death, the model may be expressed as:

$$\log_e(D_t) = \log_e(N_t) + \text{constant} + \alpha t$$

4. The population distribution by age and sex for Australia, for each State and Territory, for the Indigenous population and for urban, rural and remote areas are available on the Internet at <http://www.aihw.gov.au>.

where  $t$  is the year of registration of death,  $D_t$  is the expected number of deaths registered in year  $t$ ,  $N_t$  is the mid-year population in year  $t$ , and  $\alpha$  is the estimated annual rate of increase or decrease in mortality. This model forms the basis for the estimate of underlying trend and the statistical tests described below. The criteria for applying it to the mortality time series data were:

- the series contained non-zero deaths for at least four years (or two years for the Indigenous population), and
- the average number of deaths across the 12 years (or six years for the Indigenous population) was at least two.

Where these criteria were met, this model was fitted separately for males and females, for each age-specific group, and for the age-standardised rates (all ages and ages 25–74 and 25–64).

## Statistical tests

Two statistical tests were applied both to the age-standardised and age-specific mortality time series for males and females separately wherever the data met the above criteria for modelling. They are a ‘test for trend’, and a ‘test for difference’ to help assess whether the death rate for the most recent year is unexpected.

### Test for trend

The trend is calculated from the estimated value of  $\alpha$  from a Poisson regression model fitted to the data for all 12 years. It indicates whether death rates are generally increasing or decreasing over the period and, if so, to what extent.

Based on  $\alpha$ , an average annual rate of change has been derived as follows:

$$\text{percentage change} = [e^\alpha - 1] \times 100\%$$

The annual percentage increase (or decrease) is presented in the ‘Trend’ column under ‘Statistical tests’ and can be interpreted as the average percentage change in mortality rates between consecutive years.

A blank denotes that a model has not been fitted because the data did not meet the modelling criteria.

The test of statistical significance for the annual percentage change was two-tailed. That is, there was no prior assumption that the mortality rate would be increasing or decreasing and the alternative hypothesis was that the change in mortality rate was *different* from zero. Trends which were statistically significant at the 5% and 1% levels of significance have been indicated by asterisks.

### Test for difference

The test for difference refers to the difference between the observed and projected death rates for 1996 expressed as a percentage of the projected rate. The projected death rate for 1996 is estimated from a Poisson regression model fitted to the mortality time series for the period 1985 to 1995 (and 1991 to 1995 for the Indigenous population).

This field is left blank if a model was not fitted because the data did not meet the modelling criteria.

The test of statistical significance of the difference was two-tailed. That is, there was no prior assumption that the mortality rate for 1996 would be above or below the value predicted from the model fitted to previous years. Differences which were statistically significant at the 5% and 1% levels of significance have been indicated by asterisks.

### Significance level

Many significance tests have been performed throughout the report and it is therefore likely that some test results reported as ‘statistically significant’ are the result of chance. The possibility of a chance effect should be carefully considered when making judgement about whether statistically significant trends have sufficient medical or epidemiological importance to warrant further attention.

Some of the estimates for the Northern Territory, the Australian Capital Territory, the Indigenous population and rural and remote areas are based on small numbers and may be unstable.

## Appendix B: Tables available on the Internet

Data tables for the population distributions and for the less common causes of death for each State and Territory (for the period 1985–1996), for the Indigenous and non-Indigenous populations (for the period 1991–96), and for urban, rural and remote areas (for the period 1986–1996) are available on the Australian Institute of Health and Welfare World Wide Web site at <http://www.aihw.gov.au>. Users without Internet access may request the tables on disk by contacting AIHW reception on (02) 6244 1000. For each of the above populations the following mortality profiles have been included as separate tables:

- Rheumatic fever and rheumatic heart disease
- Hypertensive disease
- Other ischaemic heart disease
- Heart failure
- Atherosclerosis
- Peripheral vascular disease
- Other diseases of the circulatory system (defined in *Introduction* on page 2)
- All causes

For each cause of death the tables contain:

- numbers of deaths by year, age group and sex;
- age-specific death rates by year, age group and sex;
- crude and age-standardised death rates by year and sex, for all ages and ages 25–74
- annual rates of change (with indicators of statistical significance); and
- differences between the most recent death rate and that expected based on projections for that year (with indicators of statistical significance).

Where the number of deaths is less than 16 in any age-specific group, the total number of deaths are given by year and sex, in place of a full mortality profile. For the Australian Capital Territory, the Northern Territory, the Indigenous population and remote areas only the total number of deaths are given for the majority of the causes of death.

Tables containing population distributions at the national, State and Territory, Indigenous and urban, rural and remote levels are presented for each 10-year age group for males and females for the relevant years.
